Website Heatmap and User Interaction Analytics Tool

Idea Summary

Build a third-party website analytics tool that works like a thin layer over a website. Website owners install a small script, and the tool tracks how users interact with pages, including cursor movement, clicks, ignored sections, scroll behavior, and areas where users spend attention. The data becomes heatmaps and reports for marketers, designers, reviewers, and product teams.

Problem

Many teams know how many people visit a website, but they do not clearly see how users behave on the page. They may not know which buttons get attention, which sections users skip, where users hesitate, or why a page does not convert well.

Solution

Create a lightweight analytics script that can be integrated into any website. The script collects interaction signals and sends them to a dashboard. The dashboard displays heatmaps, click maps, scroll maps, and session-level insights so teams can improve layout, content, calls to action, and user experience.

How We Can Build It

Start with a JavaScript tracking snippet that records clicks, cursor movement, scrolling, viewport size, page URL, and element positions. Send the events to a backend API. Build a dashboard where website owners can select a page and view heatmap overlays. Later, add filters by device, location, traffic source, and date range.

MVP Features

- Website install script for customers.

- Click tracking and cursor movement tracking.

- Scroll-depth tracking and ignored-section detection.

- Dashboard with page list and heatmap view.

- Basic analytics report for marketers and reviewers.

- Privacy controls to avoid collecting sensitive input data.

Potential Customers

Marketing teams, website owners, ecommerce businesses, UI/UX reviewers, product teams, agencies, and startups that want to improve conversion and user experience.
